With a simple to use interface, VR-5 Image Converter enables you to do a conversion, copy, and transfer of files between devices that is safe and reliable.

Domains of aldolase reactivity of human aldolases A, B and C. The three human aldolases A, B and C were immobilized on a thiopropyl-Sepharose column. The elution patterns of the pooled aldolase preparation obtained from various tissues indicate that these enzymes vary in their degree of reactivity with different carbohydrate structures. Cross-reactivity patterns of the three aldolases obtained by affinity chromatography of microsomes fractionated from human tissues were similar to those obtained with the purified aldolases. To investigate the different substrates, membrane glycoproteins were hydrolysed with the purified enzymes immobilized on Cibachrome Sepharose. The elution patterns of the membrane glycoproteins were similar to those obtained with the purified aldolases.

Q: how to put name of column into a cell I have a rdlc report which has a matrix, i would like to have a column from a parameter in it, but it comes with the entire parameter string. Is there a way to filter it? For example I would like the string "paramName" Column A: Add a row group with a matrix in it. In the rdlc designer, set the row group to "Hide" and make it a group header. Add a text box or field that contains the parameter, and bind it to the rdlc using the Parameters collection in the code behind.

1. Field of the Invention The invention concerns a method for the operation of an electrophoretic display cell, wherein the electrophoretic display cell has a first electrode and a second electrode, a front side of the second electrode facing the front side of the first electrode and an electrode separator located between the first and second electrode which separates the front side of the first electrode from the front side of the second electrode.

2. Description of Related Art Such electrophoretic displays are known per se and are applied in many products. These known products are usually based on the principle that two differently coloured, oppositely charged, particles are applied to the electrophoretic display cell, e.g. a first particle, which is negatively charged, and a second particle, which is positively charged. When the particles are exposed to an electrical field, the first particle is made to be attracted to the second particle, which is connected to the second electrode. The position of the first particle is thus dependent on the position of the second particle. This can be used to display images in an electrophoretic display cell. In addition, other important aspects are the fastness, i.e. the "stability" and the elasticity of the displays. In particular, the stability is an important aspect for electrophoretic displays in which the particles are moved in the cells. Most

electrophoretic displays which are currently known have a display cell which is a very thin glass plate, usually between about 5 and 10 mm. This is mostly due to the fact that the glass plate on which the display cell is based is a substrate for a liquid crystal display (LCD) and the glass plate needs to have an intermediate spacing with the frame of the LCD (in which the images are displayed). As a result, the glass plate has to be a rigid plate
